The term “intermittent” has been used since the 1940s to describe human motion control as a sequence of open-loop trajectories punctuated by intermittent feedback. This seminar formulates a computational model to capture this behaviour whilst also explaining why human motion often appears to be continuous in nature. Engineering applications of intermittent control will also be discussed.

Peter Gawthrop studied Engineering Science at Oxford University where he also obtained a D.Phil. in control systems. He was Wylie Professor of Control Engineering at Glasgow University until 2002 where he is now a Senior Research Fellow. He is currently visiting NICTA Victoria Research Laboratory.
